

Magnetic chemically peculiar stars

I. Catalogue

I.I. Romanyuk

Special Astrophysical Observatory of the Russian AS, Nizhnij Arkhyz 369167, Russia

Abstract. On the basis of analysis of original publications and our own measurements a Catalogue of magnetic chemically peculiar (CP) upper main-sequence stars has been established. The sample includes 211 magnetic CP stars with magnetic fields ranging from hundreds of gauss to dozens of kilogauss, for 49 of them the surface magnetic field (B) has been measured from the Zeeman splitting.

1. Introduction

Magnetic fields of stars were discovered by Babcock in 1947. More than 50 years ago he found the Zeeman effect in the spectra of the Ap star 78 Vir. Many thousand magnetic measurements of different type stars made from young Herbig Ae/Be and T Tau stars to magnetic white dwarfs at the final stage of evolution have been made ever since.

The measurements show that magnetism is a wide-spread phenomenon among stars. As a rule, different types of bursts, explosions and other instabilities are connected with magnetic fields.

Unfortunately, magnetic field measurements are a very involved problem. For example, even the modern technique often fails to detect magnetic fields (even very strong) of complex topology.

From the late 40s to the middle 80s mainly photographic Zeeman spectra were analyzed, their low S/N ratio (20-30) did not permit fine analysis of line profiles, especially studying distribution of circular and linear polarization over the line profile.

That is why, the detection of complex structure magnetic fields (of the type of solar spots) was impossible.

Fortunately, chemically peculiar stars have ordered, mainly dipolar, very reliably measurable magnetic fields. The simple configuration of their magnetic fields leads to Zeeman shifts (very rarely to magnetic splitting) of lines as a whole, while in the case of complex non-dipolar magnetic field one needs to study the fine structure of line profiles. Results of Babcock's measurements are presented in his famous catalogue (Babcock, 1958).

Since the magnetic field value in CP stars is about a few kilogauss (which correspond to a Zeeman splitting of about 0.1-0.2 Å) only spectra of narrow-line stars can be measured for detection of magnetic fields.

The accuracy of measurements is highly dependent on the line width and therefore magnetic field measurements of fast-rotating CP stars (with $vsini > 40$ km/s) were impossible.

Photoelectric Balmer-line magnetometers were first used by Landstreet in 1970. He measured circular polarization in the wings of hydrogen lines. A Balmer magnetometer was effectively used in searching for magnetism of fast-rotating stars, hot helium-strong and helium-weak stars, magnetic white dwarfs, where photographic techniques would not be used because of the small number of broad lines in their spectra.

The results of magnetic measurements from 1958 to 1982 were collected by Didelon (1983).

Zeeman observations of CP stars provide direct evidence of magnetic fields, independently of any models. Various assumptions have certainly to be made when constructing magnetic field configuration models and field mapping.

New digital techniques: reticons and then CCD detectors permit study the line profiles with a high S/N ratio and a high spectral resolution. This made it possible to start studying magnetic field complex structure (for example, Robinson, 1980). Many new magnetic stars have been discovered, especially among cool stars.

The situation with magnetic field measurements of CP stars has also undergone essential changes: the use of CCD permits studying not only average parameters of lines (equivalent width, radial velocity, Zeeman shift), but, using the analysis of intensity and polarization profiles, also simultaneous mapping of chemical composition and magnetic field on the surface of CP stars and looking for connection between them. Separate attempts of doing this work were made earlier (for example, Khokhlova, 1983), but it is at the present time that the work has become extensive and coordinated.

A second important achievement in the study of CP stars is due to Hipparcos results. Recently the Hipparcos satellite has measured parallaxes of most of the magnetic CP stars. This permits reliable distances and, as a result, accurate absolute parameters and reliable spatial distribution of magnetic CP stars in our Galaxy to be found.

Magnetic field observations are still extremely rare: tens of thousands of stars against a few hundred magnetic stars are known to have measured radial velocities.

2. Catalogue

2.1. Fraction of CP stars

A General catalogue of Ap and Am stars, which contains almost 6700 stars, has been completed by Renson et al. (1991a), a database for 3195 Ap stars was described by Renson et al. (1991b).

The number of CP stars is essentially higher than the number of magnetic stars. More than 90% of known CP stars have never been observed with a Zeeman analyzer; most of them are faint CP stars and for their measurements one has to request time on the world's largest telescopes.

It can commonly be found in the literature that CP stars account for 10-15 % of main sequence stars of the same spectral class (e.g. see Khokhlova, 1983).

The Hipparcos team (Gomes et al., 1998) informed that among stars brighter than 7.5 mag one can find 2578 normal main-sequence stars and 467 different chemically peculiar stars in the spectral range B5-F5 in the Hipparcos catalogue. Thus we can calculate a fraction as $467/(2578 + 467) = 15.3\%$.

We have enough sufficient evidence to be certain that all chemically peculiar stars brighter than 7.5 mag have been properly classified because all bright stars have been analyzed using spectra obtained with a reasonably high spectral resolution. We can also conclude that the Hipparcos data have practically not changed the fraction of CP stars.

2.2. Catalogue of magnetic CP stars

The last published catalogue of magnetic measurements (Didelon, 1983) contains information for about 140 magnetic chemically peculiar stars. Mainly it consists of Babcock's catalogue (1958) of magnetic measurements and also photoelectric magnetic measurements of Landstreet and his co-authors.

However, during the last 15 years new data have been taken by observations with new digital devices and many new magnetic CP stars of the main sequence have been discovered.

Because Didelon's catalogue has become outdated, our purpose is to select from original papers all

possible information about magnetic measurements of CP stars, to make a new list of magnetic CP stars and to conduct a complex study of the stars from this list.

We have collected about 10000 magnetic measurements of different type main-sequence stars (published and our own). Taking into account unpublished results or ones available in the inaccessible publications, we estimate that 20000 magnetic measurements of about 300 CP and 200 normal stars have been made.

Most of them have been made by H. Babcock, G. Preston and his co-authors, J. Landstreet and his co-authors, G. Mathys with his co-authors and by the SAO group with the 6 m telescope of Russian Academy of Sciences.

Observations of most stars yield "zero-field" results: practically all normal stars (for example, Landstreet, 1982) and a large fraction of chemically peculiar stars do not show magnetic fields larger than the typical accuracy of measurements (100-300 G). For very bright narrow-line CP stars the accuracy is essentially better, since the standard error σ is about a few dozen gauss.

Publication of all measurements from our catalogue is too difficult because of the large body of collected data. Now we are making the first step only: we present a new sample of magnetic CP stars. We have included in our list only such stars, which have been found to be magnetic by the authors of the original publications.

On the basis of all collected data we have made a sample of 211 magnetic chemically peculiar stars with reliably measured magnetic fields. We present the star HD/BD number, information about the longitudinal field (B_z) extrema, surface magnetic field (B_s), number of measurements [n] and references in Table 1.

3. Conclusion

Thus we have found 211 magnetic CP stars. Surface magnetic field (B_s) estimates are available for only 49 of them. Magnetic field data for the rest of the stars (162) of our sample have been obtained from measuring the longitudinal components (B_z) alone.

For some stars the longitudinal magnetic field (B_z) magnitudes derived from data of different authors are dramatically different. Since the aim of this first paper from a series of papers to appear is to make available a list of magnetic CP stars (a detailed analysis of magnetic fields and other parameters of stars is expected to be made later on), we have decided to postpone the discussion of the differences and tabulate herein only the extreme B_z values.

A sufficiently large number (over 10) of measurements of B_s have been made for 79 magnetic CP stars,

21 of which are slow rotators with more than 10 surface magnetic field estimates. For these 21 stars reliable magnetic field models can be constructed.

The number of stars is certainly very small to comply with the requirements for observational data.

Acknowledgements. I would like to thank my colleagues from the Stellar Magnetism Laboratory of SAO RAS, V.G. Elkin and D.O. Kudryavtsev, for helpful discussions and the Russian Foundation for Basic Research for partial financial support.
